The Tools of Today

Distributed version control and git

Version control:

A system for managing changes to source data (documents, code, etc) over time.

Version control systems help you track who made what change when, and why. They also allow you to roll back changes to your data to a previous state.

Local version control

Local Computer

• Changes are tracked on a local computer

• Simple – great for working alone

• Not effective for collaboration

Centralized version control

• Single server with all versioned files; users "check out" files

• Allows for collaboration

• Single point of failure

Distributed version control

• Full mirroring of source with each user

Broadest potential for collaboration

• Complex merging, branching, etc. possible

https://git-scm.com/book/en/v2/Getting-Started-About-Version-Control

• Open source

Distributed model

• Strong User Community, lots of free documentation

• Widely used and supported across platforms

THIS IS GIT. IT TRACKS COLLABORATIVE WORK ON PROJECTS THROUGH A BEAUTIFUL DISTRIBUTED GRAPH THEORY TREE MODEL. COOL. HOU DO WE USE IT? NO IDEA. JUST MEMORIZE THESE SHELL COMMANDS AND TYPE THEM TO SYNC UP. IF YOU GET ERRORS, SAVE YOUR WORK ELSEWHERE, DELETE THE PROJECT, AND DOWNLOAD A FRESH COPY. https://xkcd.com/1597/

- Hashes all files in the repository
- \bullet Produces a diff of changes imes
- Commit messages explain who did what when and why
- Supports parallel workflows with a method for resolving conflicts

 import templates, as well as :term:`access point` names (used as subjects) in the "nameAccessPoints" column during a CSV import of ** AtON looks for creator names in the "eventActors" column in the RAD and ISAD CSV import templates, as well as :term:`access point` names (used as subjects) in the "nameAccessPoints" column during a CSV import of iterm:`archival descriptions (archival description)`. 		647	+ :align: center

docs/commit/6d8fe4ab9803ec3421b04bcabe215e3dbb4a77dc

- Essentially a (NoSQL) database
 a key/value store
 - Objects DB and Refs DB
- Libgit2: git implementation in C
 - Supports different backends
- Might git provide a model for auditable, versioned data management?

Vincent Driessen via http://nvie.com/posts/a-successful-git-branching-model/

Git for Archives?

- Description systems:
 - Maintain transparent provenance and manage collaboration and concurrency – e.g. authority records
 - Collaborative preservation environments
 - Track transfer/ingest, preservation actions
- Distributed, version-controlled backups
 - Reconcile changes via branch management

Peer to Peer computing and BitTorrent

P2P:

A **distributed** application architecture that directly links users as peers with equal privileges, instead of relying on a centralized server for communication and exchange

http://www.nextinpact.com/dossier/hadopi-nicolas-sarkozy-sacd-snep/1.htm

- A communications protocol for peer-to-peer file sharing
- Works with any kind/size of files
- Increases speed with increases in users each user becomes a potential download source
- Uses cryptographic hashing to segment files into pieces, so different pieces can be downloaded from different users and verified against the torrent tracker

- Torrent users who share content are called **peers**
- A group of peers is called a swarm
- Users who download without also sharing are called leeches
- Early BT implementations used a centralized **tracker** to discover and connect peers, before they could start sharing directly

DHT:

Distributed Hash Table. A decentralized lookup system (similar to a hash table) with key/value pairs.

- Pairs are stored in the DHT
- Any peer can look up the value associated with a key
- Responsibility for maintaining the mapping from keys to values is algorithmically distributed among the nodes to minimize disruption when nodes appear/depart/fail

• Central trackers and DHT can be used together with other methods to increase efficiency

 Other features (e.g. encryption) can be added on top

Archival uses for BitTorrent?

https://archive.org/details/bittorrent

Archival uses for BitTorrent?

Preservation requires three actions: a publisher to give permission for the target content to be preserved; for a library to bring online a LOCKSS box that has authorized access to the

🛑 dat

About Blog Team Docs

🐱 View on GitHub

Share and sync data instantly.

Dat is an open source, decentralized data tool for distributing datasets small and large.

Install now

You will need node.js to install the dat command-line tool.

npm install -g dat

http://dat-data.com/

BitTorrent, Dat shares versioned data through a decentralized network.

Dat deduplicates data between versions, reducing bandwidth costs and improving speed. There's a desktop application, a command-line tool, and a Python client library.

README.md

dat jawn: 'Git for Tabular Data'

build passing

NPM

Jawn is a node is module that allows *distributed version control of Tabular Data*. It's connected to the dat project. It allows you to import tabular data (rows and columns like CSV or TSV) and track how those data change over time. *Do you have non-tabular data? read this*: What about Non Tabular Data?

The key features for jawn are to:

- · manage and track change history in tabular data
- · create historical checkpoints with metadata (e.g., message, timestamp, author)

Jawn relies on hypercore to handle the core functions around creating merkle chains, which allows us to

- · supply access points to data across the network with a peer-to-peer model
- sync incrementally between machines

This is where jawn connects with the current work of the dat team, who created hypercore and are using it to do the same things with directories of files. For more background info, read our Technical Background and Reference Code Bases wiki page.

Project Team

jawn is maintained by a Code for Philly project that aims to be a model for mentorship and collaborative learning. For full information about the project go to the jawn project page

We welcome contributions from anyone.

https://github.com/CfABrigadePhiladelphia/jawn

- Description and access: a networking and data exchange protocol
 - Exchanging authority records between repositories
 - Updating portal sites
 - Offering content to the public
- Preservation: Sharing supporting technology images
 - Operating systems, codecs, tools
 - LOCKSS-style approach to preservation and real-time access despite service interruptions at any one point – distributed copies

The WWW

Linked data

A method of expressing and publishing structured data so that it can be interlinked and queried semantically by both humans and machines.

- Turning the web of documents into a machine-readable web of data
- From the World Wide Web to the Giant Global Graph

Linked data

4 Principles:

- Use URIs to name (identify) things.
- Use HTTP URIs so that these things can be looked up (interpreted, "dereferenced").
- **Provide useful information** about what a name identifies when it's looked up, using open standards such as **RDF**, **SPARQL**, etc.
- **Refer to other things** using their HTTP URIbased names when publishing data on the Web.

Tim Berners-Lee. John S. and James L. Knight Foundation via https://commons.wikimedia.org/wiki/File:Tim_Berners-Lee-Knight-crop.jpg

A standard model for data interchange on the web

- Makes statements about resources as expressions
- Uses subject \rightarrow predicate \rightarrow object structure to form triples

RDF

A standard model for data interchange on the web

- Uses **URIs** to express each element of the triple
- Can be serialized into many different formats

RDF

Person

Leonardo Da Vinci

Linked open data

- Make your stuff available on the Web (whatever format) under an open license
- ★ ★ Make it available as structured data (e.g., Excel instead of image scan of a table)
- Make it available in a non-proprietary
 open format (e.g., CSV instead of Excel)
- ★★★★ Use URIs to denote things, so that people can point at your stuff
- *** * * * * Link** your data to other data to provide context

http://5stardata.info/en/

5-star deployment scheme for open data

Lots of discussion, many existing useful ontologies, and some implementation in larger portal sites. Few institutional implementers out there.

- Europeana Data Model (EU), Archives Hub (UK)
- LoC, W3C, Getty; SKOS, ViAF, GeoNames, etc.
- PREMIS \rightarrow creating an OWL ontology
- PRONOM ontology? Work on hold
- ICA EGAD developing an entity relationship model that can be expressed semantically?

LINKED JAZZ API

Revealing the Relationships of the Jazz Community

Linked Jazz is a research project investigating the application of Linked Open Data technologies to digital cultural heritage materials. Our goals are:

- To uncover meaningful connections between documents and data related to the personal and professional lives of jazz artists, and
- To develop broadly applicable tools and methods for working with Linked Open Data.

Read more »

https://linkedjazz.org/

- Description and Access
 - Our systems should connect users to other related information linked data is the way
 - Relationship visualizations, queries across institutions, domains
 - Crowd-sourced description and reconciling from communities of interest
- Preservation
 - PREMIS ontology + PRONOM ontology + W3C PROV= building blocks for a community Format Policy Registry (FPR)
 - Ability to generate community-wide preservation stats

Blockchain technology

Blockchain:

A distributed ledger that uses cryptographic hashing to maintain a continuously growing record of transactions, divided into linked, time-stamped blocks.

Jorge González, "Chains reloaded." July 29, 2011. https://www.flickr.com/photos/aloriel/6292261464

- An online, anonymous cryptocurrency
- Allows peer-to-peer transactions without an intermediary
- Created 2008, released open-source in January 2009
- Relies on the **blockchain**:
 - Transactions are verified by nodes on the network
 - Nodes are rewarded for verification
 - Once transactions are verified, they are added to a block every 10mins

User installs a Bitcoin client (a wallet), and uses it to create a bitcoin address for a transaction

- A wallet can have as many BTC addresses as desired
- An address is created via public/private key cryptography

Previous hash + transaction hash + nonce = new block hash (0000000...)

- Miners (peers) try to solve the cryptographic puzzle of the nonce
- First to solve is rewarded with Bitcoin
- Other miners verify the solution
- When there is consensus, the block is added to the blockchain
- New blocks are created every 10 minutes

- An immutable, distributed, public ledger
- No single point of failure

Archival Blockchain uses?

Chain of custody

- An archival blockchain could support the maintenance provenance and authenticity
- Register acquisitions, donor agreements, transfers, preservation actions
- LOCKSS-style P2P backups use ledger + smart contracts to track who is preserving what where, under what terms – no need for centralized coordination

Archival Services Network

- Institutions donate storage space, compute power, or services
- Are rewarded with "ArchCoin" for use on the network
- These are used to cover network costs, use of other services
- DAOs and smart contracts allow automation of decentralized preservation services

Locking the Web Open: A Call for a Distributed Web

Posted on August 11, 2015 by jeff kaplan

(Short <u>form</u> article, Short <u>lecture</u>, Long <u>lecture</u>, <u>demo</u> of a fraction of the idea of a distributed website (or paste this <u>link</u> in <u>maelstrom</u>))

Over the last 25 years, millions of people have poured creativity and knowledge into the World Wide Web. New features have been added and dramatic flaws have emerged based on the original simple design. I would like to suggest we could now build a new Web on top of the existing Web that secures what we want most out of an expressive communication tool without giving up its inclusiveness. I believe we can do something quite counter-intuitive: We can lock the Web open.

One of my heroes, Larry Lessig, famously said "<u>Code is Law</u>." The way we code the web will determine the way we live online. So we need to bake our values into our code. Freedom of expression needs to be baked into our code. Privacy should be baked into our code. Universal access to all knowledge. But right now, those values are not embedded in

Decentralized Autonomous Collection

Bringing it all together

"A Decentralized Autonomous Collection is a set of digital information objects stored for ongoing re-use with the means and incentives for independent parties to participate in the contribution, presentation, and curation of the information objects outside the control of an exclusive custodian."

"...I believe that the emergence of blockchain technology and the concept of Decentralized Autonomous Organizations, alongside the maturation of peer-to-peer networks, open library technology architectures, and open-source software practices offers a new approach to the issues of control, privilege, and sustainability that are inherent to many centralized information collections."

-- Peter Van Garderen, Decentralized Autonomous Collections

Will we be a part of this future?

Group questions

- What is the **most interesting part** of this technology in terms of archives? What potential do you see?
- Where do you think these ideas **fall short**? What might be some of the challenges?
- How might the ideas shared around this technology impact your institution if it existed now? How might it change the way you carry out these workflows/activities?
- If it **doesn't** seem like it would solve a challenge you face, **why not?** What commonalities can you find in terms of challenges with others in your group?
